Lecture 22
Name Analysis Implementation
Instructor: Hossein Hojjat
March 22, 2017
Recap: Name Analysis Goals

- For each declaration of identifier, identify where the identifier refers to
- Name analysis:
  - maps, partial functions (math)
  - environments (PL theory)
  - symbol table (implementation)
- Report some simple semantic errors
- We usually introduce symbols for things denoted by identifiers
- Symbol tables map identifiers to symbols
Notations for Maps

- Mathematical notation of map is a partial function \( f : A \rightarrow B \) (that is a function from a subset of \( A \) to \( B \))
  
  \[- f \subseteq A \times B \]
  \[- \forall x. \forall y_1. \forall y_2. (x, y_1) \in f \land (x, y_2) \in f \rightarrow y_1 = y_2 \]

We define \( \text{dom}(f) = \{ x \mid \exists y. (x, y) \in f \} \)

- Sometimes we denote map \( \{(k_1, v_1), \cdots, (k_n, v_n)\} \) by \( \{k_1 \mapsto v_1, \cdots, (k_n, v_n)\} \)

- The key operation is function update
  \[ f[k := v] = \{(x, y) \mid (x = k \land y = v) \lor (x \neq k \land (x, y) \in f)\} \]
  If the value was defined before, now we redefine it

- A generalization of update is overriding one map by another
  \[ f \oplus g = \{(x, y) \mid (x, y) \in g \lor (x \notin \text{dom}(g) \land (x, y) \in f)\} \]

- Is \( f \oplus g = g \oplus f \)?
• Environment (Symbol Table): \( \Gamma = \{(x_1, T_1), \ldots, (x_n, T_n)\} \)

  identifier \quad \text{symbol (type,...)}

• \( \Gamma \vdash e \): \( e \) uses only variables declared in \( \Gamma \)

• Example: if \( \Gamma = \{(x, \text{int}), (y, \text{boolean}), (z, \text{int})\} \)
  then
  - \( \Gamma \vdash (x + 5) - z \)
  - \( \Gamma \vdash x = z + 1 \) but
  - \( \Gamma \nvdash x = w + 1 \) as \( w \) is not declared in \( \Gamma \)
Checking each variable is declared

(Variable Use)
\[
\frac{x \in \text{dom}(\Gamma)}{\Gamma \vdash x}
\]

\[
\frac{\Gamma \vdash e_1 \quad \Gamma \vdash e_2}{\Gamma \vdash e_1 + e_2}
\]

\[
\frac{\Gamma \vdash s \quad \Gamma \vdash \bar{s}}{\Gamma \vdash s; \bar{s}}
\]

\[
\Gamma \vdash x \in \text{dom}(\Gamma) \quad \Gamma \vdash e
\]
\[
\Gamma \vdash x = e
\]

\[
\frac{\Gamma \vdash e_1 \quad \Gamma \vdash e_2}{\Gamma \vdash e_1 \ast e_2}
\]

where \( s \) is statement

and \( \bar{s} \) is a statement sequence

\[
\Gamma \vdash \text{int}[x := \text{int}] \vdash \bar{s}
\]
\[
\Gamma \vdash (\text{int } x); \bar{s}
\]
int x = 0;
{
    int y = 0;
x = y - 1;
    {
        boolean x = false;
x = (y < 0);
    }
x = x + 5;
}
Γ = {(x, int)}
Γ = {(x, int), (y, int)}
Γ = {(x, boolean), (y, int)}
Γ = {(x, int), (y, int)}
Γ = {(x, int)}
Function definitions

Γ ⊕ \{(x_1, T_1), \cdots, (x_n, T_n)\} \vdash \overline{s}

\Gamma \vdash T \ m (T_1 \ x_1, \cdots, T_n \ x_n)\{\overline{s}\}

class World {
    int sum;
    int value;
    void add(int n) {
        sum = sum + n;
    }
}

Instantiating the inference rule:

\Gamma = \{(sum, int), (value, int)\}

Γ ⊕ \{(n, int)\} \vdash \text{sum} = \text{sum} + n

\Gamma \vdash \text{void add}(\text{int n}) \{\text{sum} = \text{sum} + n;\}
What kind of information do we need to store for each identifier?

**Variables (globals, fields, parameters, locals)**

- Need to know types, positions - for error messages
- Later: memory layout
  - Example: To compile $x.f = y$ into
    \[
    \text{memcpy}(\text{addr}_y, \text{addr}_x+6, 4)
    \]
  - 3rd field in an object should be stored at offset e.g. +6 from the address of the object
  - the size of data stored in $x.f$ is 4 bytes

- Sometimes more information explicit: whether variable local or global

**Classes, methods, functions**

- Recursively have their own symbol tables
• In Java, the standard model is a mutable graph of objects
• It seems natural to represent references to symbols using mutable fields (initially null, resolved during name analysis)
• Alternative way in functional languages:
  - store the backbone of the graph as a algebraic data type (immutable)
  - pass around a map linking from identifiers to their declarations
class World {
    int sum;
    void add(int foo) {
        sum = sum + foo;
    }
    void sub(int bar) {
        sum = sum - bar;
    }
    int count;
}

$\Gamma_0 = \{(\text{sum, int}), (\text{count, int})\}$

$\Gamma_1 = \Gamma_0[\text{foo := int}]$

$\Gamma_0$

$\Gamma_1 = \Gamma_0[\text{bar := int}]$

$\Gamma_0$
class World {
    int sum;
    void add(int foo) {
        sum = sum + foo;
    }
    void sub(int bar) {
        sum = sum - bar;
    }
    int count;
}

Γ₀ = \{(sum, int), (count, int)\}

Γ₁ = Γ₀[foo := int]

generate change table, record change

Γ₀ revert changes from table

Γ₁ = Γ₀[bar := int]

generate change table, record change

Γ₀ revert changes from table
Imperative Symbol Table

- Hash table, mutable $\text{Map}[\text{ID}, \text{Symbol}]$
- Example:
  - hash function into array
  - array has linked list storing (ID, Symbol) pairs

- **Undo Stack**: to enable entering and leaving scope
- Entering new scope (function, block):
  - add beginning-of-scope marker to undo stack
- Adding nested declaration (ID, sym)
  - lookup old value symOld, push old value to undo stack
  - insert (ID, sym) into table
- Leaving the scope
  - go through undo stack until the marker, restore old values
