Bagging and Boosting: the Basic Idea

Bagging

- Sample (uniformly) with replacement from the original training set
- Use unstable base classifier to develop the classifier ensemble iteratively
- Final decision is based on voting
- Boosting
 - Evolve the probability distribution of classifier ensemble to minimize the loss
 - The classifier in the ensemble is built on a training set sampled from the entire training set with updated distribution
 - Expend the classifier ensemble incrementally

Algorithm Review [Kuncheva, 2004]

Training Phase

- 1. Initialize the parameters
 - $\mathcal{D} = \emptyset$, the ensemble
 - L, the number of classifiers to train
- ▶ 2. For k = 1, ..., L
 - ► Take a bootstrap sample *S_k* from **Z**
 - Build a classifier D_k using S_k as the training set
 - Add the classifier to the current ensemble, $\mathcal{D} = \mathcal{D} \cup D_k$
- ▶ 3. Return D

Classification Phase

- 4. Run $D_1, ..., D_L$ on the input *mathbfx*
- 5. The class with the maximum number of votes is chosen as the label for mathbfx

Technique Highlight

- The bootstrap sampling with replacement is drawn from the training set Z with the same uniform distribution
- Bagging is a linear combination of classifiers derived from a single base classifier:
 - Majority voting (hard-labeling in the case of binary classification)
 - Soft-combination with weighted output (soft-labeling in the case of binary classification)

When we keep increasing the size of 200 training-set ensemble:

Romanczyk & Wang

Outline

Interpretation by Bias-Variance Decomposition [Fumera et al., 2008]

- Average error: $E = E_{bayes}^2 + E_{bias}^2 + V$
- Bagging reduce the variance by increasing the ensemble size

•
$$E_{add} = E_{bias}^2 + V = E_T \{ E^2(x; t_B) + \frac{1}{m} V(x; t_B) \}$$

Questions

Boosting

- Run multiple classifiers
- Weight the classifiers by how well they perform.
- Unstable classifiers are ideally suited to boosting algorithms that subsample the training data.

$\mathsf{HEDGE}(\beta)$

Given:

- $\mathcal{D} = \{D_1, \dots, D_L\}$ $\mathbf{Z} = \{\mathbf{z}_1, \dots, \mathbf{z}_N\}$
- 1. Initialize the parameters
 - Pick $\beta \in [0,1]$
 - Set weights $\mathbf{w}^1 = [w_1, \dots, w_L], w_i^1 \in [0, 1], \sum_{i=1}^N w_i^1 = 1$ (Usually $w_i^1 = \frac{1}{I}$)

$\mathsf{HEDGE}(\beta)$

- 2. For all \mathbf{z}_j , $j = 1, \ldots, N$
 - Calculate the distribution by

$$p_i^j = \frac{w_i^j}{\sum_{k=1}^L w_k^j}, i = 1, \dots, L$$

- ► Find the individual losses: l_i^j = 1 if D_i produces a misclassification of z_j and l_i^j = 0 otherwise, i = 1,..., L)
- Update the cumulative loss

$$\Lambda \leftarrow \Lambda + \sum_{i=1}^{L} p_i^j l_i^j$$

Update the individual losses

$$\lambda_i \leftarrow \lambda_i + l_i^j$$

Update the weights

$$w_i^{j+1} = w_i^j \beta^{l_i^j}$$

Adaptive Boosting

Training

- 1. Initialize the parameters
 - Set weights $\mathbf{w}^1 = [w_1, \dots, w_N], w_j^1 \in [0, 1], \sum_{j=1}^N w_j^1 = 1$ Initialize the ensemble $\mathcal{D} = \emptyset$

- Pick the number of classifiers to train, L

Romanczyk & Wang

Outline

Boosting Examples

AdaBoost

2. For k = 1, ..., L

- Take a sample S_k from **Z** using distribution \mathbf{w}^k
- Build a classifier D_k using S_k as a training set
- Calculate the weighted ensemble error at step k by $\epsilon_k = \sum_{j=1}^N w_j^k l_k^j$ where $l_j^k = 1$ if D_k produces a misclassification of \mathbf{z}_j and $l_i^k = 0$ otherwise.
- If $\epsilon_k = 0$ or $\epsilon_k \ge 0.5$, ignore D_k , reinitialize the weights w_i^k to 1/N and continue.
- Else calculate $\beta_k = \frac{\epsilon_k}{1 \epsilon_k}$, $\epsilon_k \in (0, 0.5)$
- Update the individual weights $w_j^{k+1} = \frac{w_j^k \beta^{(1-l_k^j)}}{\sum_{i=1}^N w_j^k \beta^{(1-l_k^j)}}$,
